76 F w/ delirium/confusion

Daniel Chen, MD
Elena Violari, MD
Leo Wolansky, MD
Chronic subdural hematoma
- Crescent shaped extra-axial collection
- Can cross sutures but not dural attachments
- Density varies with age of infarct – heterogeneity common
• Mass effect with midline shift and subfalcine herniation

• Enhancing internal membranes or septations are common
Chronic subdural hematoma

- Crescentic extraaxial collection that spreads diffusely
- Mechanism - trauma
- Most commonly supratentorial
- Often septated, with enhancing membranes
- Mixed-age hemorrhage common
- In contrast enhanced studies, cortical vessels are inwardly displaced
Chronic subdural hematoma

-Most commonly hyperintense on T1, T2, PD, -FLAIR, although signal is variable in intensity depending on chronicity

-Differential includes subdural hygroma (non-enhancing, no membranes, CSF density), subdural effusion (associated w/ meningitis)
